

Manufacturing of Recycled Polyester Fiber from used PET Bottles

Description:

Manufacturing of Recycled Polyester Fiber from used PET Bottles. Recycling Plastic Bottle into Synthetic Fiber.

Polyester may be a manmade fibre, synthesized from petrochemical products by a process called polymerization. Polyester springs from crude oil petroleum and may be a non-natural resource. It's processed through a system called 'cracking' which treats the petroleum through intensive heating and cooling, fuel, solvents, pressure and catalysts to interrupt down the molecular structure.

The most common variety of recycled polyester is understood as rPET, which comes from discarded clear plastic bottles rather than raw petrochemicals. Polyester fabric recycling, where the particular polyester yarn is recycled, is a smaller amount common. During this case, polyester scraps and textiles are broken down into fibre components which will then be spun into the recycled yarns.
